Tashkent, Uzbekistan

Abstract

Our epidemiological survey is the first step in studying prevalence and risk factors of postmenopausal osteoporosis (PMO) in the Republic of Uzbekistan, aiming at development of early preventive and therapeutic measures to reduce osteoporosis-associated fractures.

Methods: We screened 1378 postmenopausal female residents of Tashkent and Namangan, two cities with the largest populations in Uzbekistan, aged from 50 to 80. The duration of the postmenopausal period was ≥1 year.

Results: According to our data, the prevalence of osteoporosis in different regions of Uzbekistan varies widely (33.5% and 51.1% in Tashkent and Namangan, respectively). The prevalence of osteoporosis increases with age from 25.6% (50 to 59 years) to 51.3% (in >70 age group) in Tashkent and from 44.0% to 80.0% in the same age groups in Namangan.

There were significantly more women in Namangan with body mass <57 kg than in Tashkent (OR 2.44; 95%CI 1.72-3.46; P<0.00001). We found that the number of women doing physical exercises in Tashkent was 2 times more than in Namangan (65.5% versus 36.1%; OR 3.36; 95% CI 2.64-4.27; P<0.0001).

Conclusion: Our research shows that osteoporosis is widely spread among women above 50 living in two big densely populated cities of Uzbekistan (Tashkent and Namangan). Low body mass and irregular physical activity, fracture history, and duration of menopause are the factors of risk in the studied cohorts of women.

Keywords: menopause; risk factors; osteopenia; osteoporosis.

Introduction

Postmenopausal osteoporosis (PMO) is a systemic, multifactorial skeletal disease occurring in women in postmenopause as a consequence of deficiency of sexual hormones, mainly estrogens. The disease is characterized by progressive loss of bone mass and change in microstructure, resulting in increased risk of fracture, morbidity, and mortality. PMO constitutes up to 80% to 85% of all types of osteoporosis [1-3]. Osteoporosis frequency in all skeletal sites increases with age; thus, according to WHO, osteoporosis is registered in 70% of women older than 80 years [4]. Findings from epidemiological studies in the Russian Federation demonstrated that in the age group of ≥50 years, according to WHO criteria, osteoporosis occurred in 30.5% to 35.1% of women and in 22.8% to 24.1% of men, totaling 10 million people [5], which means that 1 woman out of 5 and 1 man out of 3 have osteoporosis. Similar data were published on prevalence of osteoporosis among women of the white population of North America and a number of countries of Western Europe [6-8]. Frequency of osteopenia and osteoporosis among perimenopausal female residents of Tashkent is 55.7% and 12.2%, respectively [9]. But no epidemiological studies of postmenopausal osteoporosis have been conducted in the Republic of Uzbekistan so far.

According to the U.S. Census Bureau International Database, in 2014 the population of Uzbekistan was 29 million people, 17% (4.2mln) and 3.4% (971,000) of people being ≥50 and ≥70 years of age, respectively. By 2050 in the face of a general population rise to 35 million people, 40% (14mln) and 12% (4.2mln) are expected to be ≥50 and ≥70 years of age, respectively. No specially designed epidemiological studies of
osteoopenia, and the value ≤ -1.0 SD was taken as normal. Thus, osteoporosis was diagnosed with T-score of 2.5 SD, the number of standard deviations (SD) from age norm.

The work was initiated to study prevalence and various risk factors of postmenopausal osteoporosis among female residents of Tashkent and Namangan.

Materials and methods

We screened 1378 postmenopausal female residents of Tashkent and Namangan, two cities with the largest populations in Uzbekistan, aged from 50 to 80. The duration of the postmenopausal period was ≥1 year. The groups were comparable by parameters. Duration of osteoporosis and menopause ≥1 year was the inclusion criterion. Diseases affecting bone metabolism, such as hyperparathyroidism, thyrotoxicosis, Itsenko-Cushing’s syndrome and disease, hypogonadism in medical history, rheumatic disorders, malabsorption syndrome, renal insufficiency, hepatic dysfunction, and malignancies, as well as prior treatment with medications affecting calcium metabolism 12 months before the study, were the exclusion criteria.

The study was conducted in accordance with the ethical principles stated in Declaration of Helsinki of 1964 (revised in Seoul in 2008). The trail is registered on www.who.int/bulletin/archives/79(4)373;http://www.wma.net/en/30publications/10policies/b3/. The study was approved by the Center for the Scientific and Clinical Study of Endocrinology Ethics Committee. Written informed consent was obtained from all participants. A special questionnaire chart was developed in the Center and was filled out for each woman. The chart included demographic and anthropometric data (age, height, weight), gynecological and hormonal history (age of menarche, age of menopause, the number of children, reproductive history), private and familial history of fractures, the present way of life (physical activity, smoking, drinking, and everyday use of dairy products).

Bone mineral density (BMD) was measured by ultrasound osteodensitometry (Omnisense 8000, Sunlight, Israel).

According to clinical guidelines, diagnosis of osteoporosis or osteopenia was based on the values of a T-score, the number of standard deviations (SD) from age norm. Thus, osteoporosis was diagnosed with T-score of 2.5 SD, the parameter’s range from >-2.5 SD to ≤ 1.0 SD determined osteopenia, and the value < -1.0 SD was taken as normal. Every patient filled in a card-questionnaire developed at the Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Health Ministry.

Results were statistically processed using Excel 2010 and the software package STATISTICA 6.0 (Stat Soft, 2001). Logistic regression was used to calculate OR and 95% CI. Quantitative parameters are presented as M±SD, as well as Median (Me) and 25th and 75th percentiles as Inter Quartile Range (IQR). We used the Chi-square test to compare observed data. P values of <0.05 were considered statistically significant.

Results

We screened 1378 postmenopausal female residents aged ≥ 50 years (mean age 57.9 ± 6.4 years, IQR 53.0 to 62.0) within the period from 05.01.2010 to 05.01.2011. Residents of Tashkent were placed into Group 1 (n=963), and residents of Namangan into Group 2 (n=415). Among the examinees 371 (26.9%) women had normal BMD (nBMD), while osteopenia and osteoporosis were diagnosed in 473(34.3%) and 534 (38.8%) examinees, respectively (Table 1).

*P < 0.0001
The maximum number of women with nBMD was found in the age group of 50 to 59 years (80.6%). With ageing, a progressive reduction in the percentage of patients with normal parameters was observed: 17.5% and 1.89% in the age groups of 60 to 69 and 70 to 79 years, respectively. In women with osteopenia the tendency persists, but there were significantly fewer women aged from 50 to 59 years in the osteopenia group than in the group with nBMD (62.8% versus 80.6%; OR 0.41; 95%CI 0.30-0.56; \(P<0.0001\)). There were significantly more women aged from 60 to 69 (OR 2.0; 95%CI 1.43-2.79; \(P<0.0001\)) and from 70 to 79 (OR 4.16; 95%CI 1.82-9.47; \(P<0.0001\)) years in the group with osteopenia than in the group with nBMD.

In the osteoporosis group there were confidently fewer women aged from 50 to 59 (53.6%) than in the group with nBMD (OR 0.28; 95%CI 0.2-0.38; \(P<0.0001\)) and in the group with osteopenia (OR 0.68; 95%CI 0.53-0.88; \(P<0.0001\)). However, among examinees with osteoporosis there were confidently fewer women aged from 60 to 69 (36.0%) than in the group with nBMD (OR 2.64; 95%CI 1.92-3.64; \(P<0.0001\)) and in the osteopenia group (OR 1.32; 95%CI 1.01-1.72; \(P=0.05\)).

About 10.5% of women with osteoporosis belonged to the 70- to 79-year-old group; they were confidently more in number than in the group with nBMD (OR 6.09; 95%CI, 2.74-13.5; \(P<0.0001\)) and more, though not confidently, than in the group with osteopenia (OR 1.47; 95%CI 0.94-2.28; \(P=0.11\)). As to residency, there were confidently fewer women with nBMD in Namangan than in Tashkent (18.1% versus 30.7%, OR 0.50; 95%CI 0.37-0.66; \(P<0.0001\)). In addition, osteoporosis in Group 2 was found in 51.1% of examinees from Namangan versus 33.5% in those from Tashkent (OR 2.08; 95%CI 1.64-2.63; \(P<0.0001\)) (Fig. 1).

Figure 1. Frequency of BMD disorders among residents of Tashkent and Namangan

Namangan residents in the 50 to 59 and the 60 to 69 age groups were 1.5 and almost 5 times less than Tashkent residents, respectively. Similarly, a low frequency of nBMD could be seen in women aged from 70 to 79. Prevalence of osteopenia was found not to depend on age in Tashkent residents. The number of osteopenia cases confidently reduced among examinees from Namangan. With ageing, the number of women with osteoporosis was found to increase in both cities, but among Namangan residents the number was almost 2 times more. Thus, osteoporosis frequency was higher in the Namangan group than in the Tashkent group. In Namangan, nBMD was found in fewer female residents, and osteoporosis frequency was higher.

By means of analysis of BMD dependence on age, we found that the mean age of the examinees was 57.9±6.4 years; the Tashkentian examinees were significantly older than Namanganians (59.4±6.4 versus 55.4±5.8). This tendency was confirmed by more detailed analysis of the dependence of the degree of BMD on age. However, despite the fact that among examinees in the second group osteopenia and osteoporosis frequencies were higher, the women on average were 3 to 6 years younger than those in the first group.

There were significantly more women in Namangan with weight <57 kg than in Tashkent (OR 2.44; 95%CI 1.72-3.46; \(P<0.00001\)) (Fig. 2.). There were more patients with low BMI in the cohort of Namangan residents with osteopenia and osteoporosis. Comparative analysis of parameters in the two cities demonstrated more women with lower limit of weight in Namangan. This seems to be the cause of higher osteopenia and osteoporosis in Group 2. We have found no substantial differences in the rate of BMI<20.0 kg/m\(^2\) in the studied cohort of women (OR 1.72; 95%CI 0.78-3.78; \(P=0.25\)). Neither irregular administration of calcium nor smoking made a significant difference.

Figure 2. The percentage of women with weight less than 57 kg depending on the bone mineral density

Regular physical activity among women with osteoporosis was significantly rarer than in women with nBMD (48.1% versus 64.4%, OR 0.51; 95%CI 0.39-0.67; \(P<0.0001\)). At the same time, the number of women doing physical exercises in Tashkent was 2 times more than in Namangan (65.5% versus 36.1%, OR 3.36; 95%CI 2.64-4.27; \(P<0.0001\)). Tashkent female residents with osteoporosis were physically active more regularly than Namangan female residents (62.4% versus 26.4%, OR 4.63; 95%CI 3.17-6.76; \(P<0.0001\)). In Namangan, the percentage of physically active women in the osteoporosis group (26.4%) was confidently lower than those in nBMD group (49.3%, OR 0.37; 95%CI 0.21-0.64; \(P<0.0001\)) and in the osteopenia group (44.5%, OR 0.45; 95%CI 0.28-0.71; \(P<0.0001\)).

We studied osteoporosis frequency by duration of menopause. In Namangan, there were more women with menopause onset before 45 years of age than in Tashkent
(30.8% versus 14.2%, OR 2.69; 95% CI 2.04-3.54; P<0.0001). There were many more nBMD women with a menopause duration less than 5 years compared to PMO women (45.0% versus 20.8% OR 3.13; 95% CI 2.26-4.32; P<0.0001). It was much more frequent among residents from Tashkent (52.4% versus 15.2%, OR 6.09; 95% CI 3.98-9.32; P<0.0001) than from Namangan (30.1% versus 31.7%, OR 0.93; 95% CI 0.54-1.59; P=0.89). Osteoporosis was confidently more frequent among patients with menopause duration more than 10 years (51.7% versus 14.3%, OR 6.11; 95% CI 4.61-8.11; P<0.0001).

Discussion

Osteoporosis has become a major public health concern, which leads to increased rates of morbidity and mortality. Epidemiological investigations have shown that there is no country, nationality or race free from osteoporosis. According to NHANES data, there are 14 million women in the US aged more than 50 with low hip bone density. Prevalence of osteoporosis in all parts of the skeleton rises with age. According to WHO data, it exists in 70% of women more than 80 years old [10]. The disorder is being diagnosed in all age groups (from 6% in individuals >50 years to 50% among individuals >80 years) [11]. A recent study on the epidemiology of osteoporosis in the United States found a prevalence of 15.4% among women older than 50 years and a prevalence of 34.9% among women older than 80 years [12].

According to our data, the prevalence of osteoporosis in different regions of Uzbekistan varies widely (33.5% and 51.1% in Tashkent and Namangan, respectively). The prevalence of osteoporosis increases with age from 25.6% (50 to 59 years) to 51.3% (in >70 age group) in Tashkent and from 44.0% to 80.0% in the same age groups in Namangan.

Low weight or low BMI is an indicator of low mineral density of bone tissue and a predictor of future fractures, particularly of the hip. Low BMI is <20 kg/m², low BMD - <57 kg [13,14]. Our data show that there were many more residents with body mass <57 kg in Namangan, than in Tashkent, but there was no difference in the number of residents with BMI<20 kg/m².

A low intake of calcium can lead to increased resorption of the bone matrix with demineralization and a consequent increase in fracture risk [1]. There were an equal number of women in studied cohorts using dairy products.

Persistent low physical activity is known to facilitate osteoporosis in older years. A sedentary style of life and immobilization result in rapid bone mass loss associated with accelerated bone resorption and slow bone formation [15]. Our study showed that the number of women doing physical exercises in Tashkent was 2 times more than in Namangan (65.5% versus 36.1%, OR 3.36; 95% CI 2.64-4.27; P<0.0001). According to Van Geel [16,17], the risk of re fracture increases if the previous fracture took place less than 5 years ago. According to our data from two densely populated regions, fractures occurred much more frequently in Namangan (6.02% versus 1.7%, OR 3.79; 95% CI 2.0-7.18; P<0.0001). Menopause and its duration is the most significant osteoporosis risk factor. After the onset of menopause, bone mass loss is nearly 2% to 3% a year up to the age of 65 to 70, the rate subsequently reducing to 0.3% to 0.5% a year [18]. We found that the frequency of women with nBMD substantially decreases as the duration of menopause increases.

Conclusion

Our research shows that osteoporosis is widely spread among women above 50 living in two big densely populated cities of Uzbekistan (Tashkent and Namangan). Osteoporosis prevalence among Namangan female residents is higher than among Tashkent residents (51.1% versus 33.5%), the former being 3 to 6 years younger than the latter. Low body mass and irregular physical activity, fracture history, and duration of menopause are the factors of risk in the studied cohorts of women.
